The past two decades have witnessed an enormous progress in our understanding of plastid (chloroplast) biology. Basic principles of plastid biogenesis, genome structure and function, gene expression and its regulation as well as plastid-nuclear interaction and communication pathways have been elucidated.

The plastid genomes of these algae contain many more genes than those of metaplyte (land plant) plastids, and the encoded proteins are involved in a much wider range of metabolic activities. Rhodophyte and chromophyte plastid genomes contain very few introns and maintain many ancestral gene operons, which suggests that they are more primitive than those of metaplytes.

Plastids are not created de novo, but arise by division from pre-existing plastids in the cytoplasm through binary fission. Because of this, plastid division is of paramount importance, not only for the maintenance of plastid populations in dividing plant cells but also in the accumulation of large numbers of chloroplasts in photosynthetic cells, presumably to maximize photosynthesis.

The cellular subgenomes in nucleus, mitochondria and plastids communicate in a complex way and co/evolve. The application of hybrid and cybrid technologies, most notably those involving interspecific exchanges of plastid and nuclear genomes, has uncovered a multitude of species-specific nucleo/organelle interactions.

The role of plastids in plant speciation—GREINER—2011...
Plastids are double-membrane organelle which are found in the cells of plants and algae. Plastids are responsible for manufacturing and storing of food. These often contain pigments that are used in photosynthesis and different types of pigments that can change the colour of the cell.
